Dedicated to James D. Louck on the Occasion of His Seventy-Fifth Birthday

Abstract

We present a method to prove hypergeometric double summation identities. Given a hypergeometric term $F(n, i, j)$, we aim to find a difference operator $L = a_0(n)N^0 + a_1(n)N^1 + \cdots + a_r(n)N^r$ and rational functions $R_1(n, i, j), R_2(n, i, j)$ such that $LF = \Delta_i(R_1F) + \Delta_j(R_2F)$. Based on simple divisibility considerations, we show that the denominators of $R_1$ and $R_2$ must possess certain factors which can be computed from $F(n, i, j)$. Using these factors as estimates, we may find the numerators of $R_1$ and $R_2$ by guessing the upper bounds of the degrees and solving systems of linear equations. Our method is valid for the Andrews-Paule identity, the Carlitz’s identities, the Apéry-Schmidt-Strehl identity, the Graham-Knuth-Patashnik identity, and the Petkovšek-Wilf-Zeilberger identity.

AMS Classification: 33F10, 68W30

Keywords: Zeilberger’s algorithm, double summation, hypergeometric term

1. Introduction

This paper is concerned with double summations of hypergeometric terms $F(n, i, j)$. A function $F(n, k_1, \ldots, k_m)$ is called a hypergeometric term if the quotients

$$\frac{F(n+1, k_1, \ldots, k_m)}{F(n, k_1, \ldots, k_m)}, \quad \frac{F(n, k_1 + 1, \ldots, k_m)}{F(n, k_1, \ldots, k_m)}, \quad \ldots, \quad \frac{F(n, k_1, \ldots, k_m + 1)}{F(n, k_1, \ldots, k_m)}$$

are rational functions of $n, k_1, \ldots, k_m$. Throughout the paper, we use $N$ to denote the shift operator with respect to the variable $n$, given by $NF(n) =$
F(n + 1) and use \( \Delta_x \) to denote the difference operator with respect to the variable \( x \), given by \( \Delta_x F = F(x + 1) - F(x) \). For polynomials \( a \) and \( b \), we denote by \( \gcd(a, b) \) their monic greatest common divisor. When we express a rational function as a quotient \( p/q \), we always assume that \( p \) and \( q \) are relatively prime unless it is explicitly stated otherwise.

Zeilberger’s algorithm [13, 16, 21], also known as the method of *creative telescoping*, is devised for proving hypergeometric identities of the form

\[
\sum_k F(n, k) = f(n), \tag{1.1}
\]

where \( F(n, k) \) is a hypergeometric term and \( f(n) \) is a given function. This algorithm has been used to deal with multiple sums by Wilf and Zeilberger [20]. Given a hypergeometric term \( F(n, k_1, \ldots, k_m) \), the approach of Wilf and Zeilberger is to try to find a linear difference operator \( L \) with coefficients being polynomials in \( n \)

\[
L = a_0(n)N^0 + a_1(n)N^1 + \cdots + a_r(n)N^r
\]

and rational functions \( R_1, \ldots, R_m \) of \( n, k_1, \ldots, k_m \) such that

\[
LF = \sum_{l=1}^{m} \Delta_{k_l}(R_l F). \tag{1.2}
\]

As noted by K. Wegschaider [19], when the boundary conditions are admissible, Equation (1.2) leads to a homogenous recursion for the multissummations:

\[
L \sum_{k_1, \ldots, k_m} F(n, k_1, \ldots, k_m) = 0.
\]

When \( m = 1 \), \( L \) and \( R_1 \) can be solved by Gosper’s algorithm [12, 16]. S.A. Abramov, K.O. Geddes and H.Q. Le also provided a lower bound for the order \( r \) [2,3] and found a faster algorithm [4] compared with Zeilberger’s algorithm. For a survey on recent developments, see [1]. For \( m \geq 2 \), constructing the denominators of \( R_1, \ldots, R_m \) for the Wilf-Zeilberger approach remains an open problem. In a recent paper [15], M. Mohammed and D. Zeilberger used the denominator of \( LF/F \) as the estimate of the denominators of \( R_i \). In an alternative approach, Wegschaider generalized Sister Celine’s technique [19] to multiple summations, and proved many double summation
identities. A different approach has been proposed by F. Chyzak [10, 11] by finding recursions of the summation iteratively starting from the inner sum. C. Schneider [17] presented the Chyzak method from the point of view of Karr’s difference field theory.

In this paper, we provide estimates of the denominators of $R_1$ and $R_2$ for double summations. These estimates turn out to be good enough for several double summation identities, including the Andrews-Paule identity for which our approach seems to be more suitable than Wegschaider’s approach. It should be noted that the algorithm of Mohammed and Zeilberger sometimes gives higher order of recursions. In this sense, our method can be regarded as an improvement of the algorithm of Mohammed and Zeilberger.

To give a sketch of our approach, we first consider Gosper’s algorithm for bivariate hypergeometric terms. Suppose that $F(i, j)$ is a hypergeometric term and $p_1/q_1, p_2/q_2$ are rational functions such that

$$F(i, j) = \Delta_i \left( \frac{p_1(i, j)}{q_1(i, j)} F(i, j) \right) + \Delta_j \left( \frac{p_2(i, j)}{q_2(i, j)} F(i, j) \right).$$

We show that under certain hypotheses (Section 2, (H1)–(H3)), the denominators $q_1, q_2$ can be written in the form

$$q_1(i, j) = v_1(i) v_2(j) v_3(i + j) v_4(i, j) u_1(j) u_2(i, j),$$
$$q_2(i, j) = v_1(i) v_2(j) v_3(i + j) v_4(i, j) w_1(j) w_2(i, j),$$

such that $v_1, v_2, v_4$ and $u_2, w_2$ are bounded in the sense that they are factors of certain polynomials which can be computed for a given $F(i, j)$, see Theorem 2.1. Then we apply these estimates to the telescoping algorithm for double summations. Suppose that

$$LF(n, i, j) = \Delta_i \left(R_1(n, i, j) F(n, i, j) \right) + \Delta_j \left(R_2(n, i, j) F(n, i, j) \right),$$

where

$$R_1(n, i, j) = \frac{1}{d(n, i, j)} \cdot \frac{f_1(n, i, j)}{g_1(n, i, j)}, \quad R_2(n, i, j) = \frac{1}{d(n, i, j)} \cdot \frac{f_2(n, i, j)}{g_2(n, i, j)},$$

and $d(n, i, j)$ is the denominator of $LF(n, i, j)/F(n, i, j)$. We may deduce that $g_1, g_2$ can be factored in the form of (1.3) such that $v_1, v_2, v_4$ and $u_2, w_2$...
are bounded, see Theorem 3.1. Although we do not have the universal denominators, these bounds can be used to give estimates of the denominators $g_1$ and $g_2$. Then by further guessing the bounds of the degrees of the numerators of $R_1$ and $R_2$, we get the desired difference operator if we are lucky.

Indeed, our approach works quite efficiently for many identities such as the Andrews-Paule identity, Carlitz’s identities, the Apéry-Schmidt-Strehl identity, the Graham-Knuth-Patashnik identity, and the Petkovšek-Wilf-Zeilberger identity.

2. Denominators in Bivariate Gosper’s Algorithm

For a given bivariate hypergeometric term $F(i, j)$, we give estimates of the denominators of the rational functions $R_1(i, j), R_2(i, j)$ satisfying

$$F(i, j) = \Delta_i (R_1(i, j) F(i, j)) + \Delta_j (R_2(i, j) F(i, j)).$$

Let

$$R_1(i, j) = \frac{f_1(i, j)}{g_1(i, j)}, \quad R_2(i, j) = \frac{f_2(i, j)}{g_2(i, j)},$$

$$\frac{F(i + 1, j)}{F(i, j)} = \frac{r_1(i, j)}{s_1(i, j)}, \quad \frac{F(i, j + 1)}{F(i, j)} = \frac{r_2(i, j)}{s_2(i, j)}.$$  \hfill (2.2)

Dividing $F(i, j)$ on both sides of (2.1) and substituting (2.2) into it, we derive that

$$1 = \frac{r_1(i, j) f_1(i + 1, j)}{s_1(i, j) g_1(i + 1, j)} - \frac{f_1(i, j)}{g_1(i, j)} + \frac{r_2(i, j) f_2(i, j + 1)}{s_2(i, j) g_2(i, j + 1)} - \frac{f_2(i, j)}{g_2(i, j)}. \hfill (2.3)$$

Let

$$u(i, j) = \gcd(s_1(i, j), s_2(i, j)), \quad v(i, j) = \gcd(g_1(i, j), g_2(i, j)),$$

and

$$s'_1(i, j) = s_1(i, j)/u(i, j), \quad s'_2(i, j) = s_2(i, j)/u(i, j),$$

$$g'_1(i, j) = g_1(i, j)/v(i, j), \quad g'_2(i, j) = g_2(i, j)/v(i, j). \hfill (2.4)$$

We find that in many cases we can restrict our attention to those $R_1, R_2$ whose denominators $g_1, g_2$ satisfy the following three hypotheses which lead
simple divisibility properties. It turns out that these divisibility requirements are sufficient to give good estimates for the denominators $g_1$ and $g_2$. The three hypotheses are as follows:

(H1) Suppose $p(i, j)$ and $p(i+h_1, j+h_2)$ are both irreducible factors of $g_1(i, j)$ ($g_2(i, j)$, respectively) for some $h_1, h_2 \in \{-1, 0, 1\}$. Then they must coincide.

(H2) $\gcd(g'_1(i, j), v(i, j)) = \gcd(g'_2(i, j), v(i, j)) = 1$.

(H3) For any integers $h_1, h_2 \in \{-1, 0, 1\}$,

$$\gcd(g'_1(i + h_1, j + h_2), g'_2(i, j)) = 1.$$ 

For example, the following functions satisfy the above hypotheses:

$$g_1(i, j) = (2n-2i+1)(n-i+1)(j+1)^2, \quad g_2(i, j) = (2n-2i+1)(n-i+1)(i+1)^2.$$ 

Under the above hypotheses, we have

**Theorem 2.1** The denominators $g_1(i, j), g_2(i, j)$ can be factored into polynomials:

$$g_1(i, j) = v_1(i)v_2(j)v_3(i+j)v_4(i, j)u_1(j)w_2(i, j),$$

$$g_2(i, j) = v_1(i)v_2(j)v_3(i+j)v_4(i, j)w_1(i)w_2(i, j),$$

such that

$$v_1(i) | r_1(i - 1, j)s'_2(i - 1, j),$$

$$v_2(j) | r_2(i, j - 1)s'_1(i, j - 1),$$

$$v_4(i, j) | \gcd(r_1(i - 1, j)s'_2(i - 1, j), r_2(i, j - 1)s'_1(i, j - 1)),$$

$$w_2(i, j) | \gcd(s_1(i, j)s'_2(i, j), r_1(i - 1, j)s'_1(i - 1, j)),$$

$$w_2(i, j) | \gcd(s_2(i, j)s'_1(i, j), r_2(i, j - 1)s'_1(i, j - 1)).$$

**Proof.** Substituting (2.4) into (2.3), we get

$$1 = \frac{r_1(i, j)}{s'_1(i, j)u(i, j)g'_1(i + 1, j)v(i + 1, j)} - \frac{r_1(i, j)}{g'_1(i, j)v(i, j)} + \frac{r_2(i, j)}{s'_2(i, j)u(i, j)g'_2(i, j + 1)v(i, j + 1)} - \frac{r_2(i, j)}{g'_2(i, j)v(i, j)}.$$
That is,
\[ s_1(i, j)s'_2(i, j)g_1(i, j)g'_2(i, j)g_1(i + 1, j)g_2(i, j + 1) = f_1(i + 1, j)r_1(i, j)s'_2(i, j)g_1(i, j)g'_2(i, j)g_1(i + 1, j)g_2(i, j + 1) \]
\[ - f_1(i, j)s_1(i, j)s'_2(i, j)g'_2(i, j)g_1(i + 1, j)g_2(i, j + 1) + f_2(i, j + 1)r_2(i, j)s'_1(i, j)g_1(i, j)g'_2(i, j)g_1(i + 1, j) \]
\[ - f_2(i, j)s_1(i, j)s'_2(i, j)g'_1(i, j)g_1(i + 1, j)g_2(i, j + 1). \]

1. Suppose \( p(i, j) \) is an irreducible factor of \( v(i, j) \), and for some non-negative integer \( l \), \( p^l | v \). Note that \( p(i + h_1, j + h_2) \) is also irreducible. Since
\[ \gcd(p(i + 1, j), f_1(i + 1, j)) = \gcd(p(i, j + 1), f_2(i, j + 1)) = 1, \]
we have
\[ p^l(i + 1, j) | r_1(i, j)s'_2(i, j)g_1(i, j)g'_2(i, j)g_1(i + 1, j)g_2(i, j + 1) \]
and
\[ p^l(i, j + 1) | r_2(i, j)s'_1(i, j)g_1(i, j)g'_2(i, j)g_1(i + 1, j). \]

There are three cases:

- \( p(i, j) \) is a polynomial depending only on \( i \). Then \( \gcd(p(i + 1, j), g_1(i, j)) = 1 \). Otherwise, by hypothesis (H1) we have that \( p(i + 1, j) = p(i, j) \) is independent of \( i \), which is a contradiction. Similarly, \( \gcd(p(i + 1, j), g_2(i, j)) = 1 \). Since \( p(i, j) \) is a polynomial depending only on \( i \), we have
\[ \gcd(p(i + 1, j), g_2(i, j + 1)) = \gcd(p(i + 1, j + 1), g_2(i, j + 1)) = 1. \]

Hence,
\[ p^l(i + 1, j) | r_1(i, j)s'_2(i, j). \]
Let \( v_1(i) \) denote the product of all irreducible factors of \( v(i, j) \) that depend only on \( i \). Then we have (2.5).

- \( p(i, j) \) is a polynomial depending only on \( j \). The same discussion leads to
\[ p^l(i, j + 1) | r_2(i, j)s'_1(i, j). \]
Let \( v_2(j) \) denote the product of all irreducible factors of \( v(i, j) \) that depend only on \( j \). Then we have (2.6).
• $p(i, j)$ is a polynomial depending both on $i$ and on $j$. Then either

\[ p(i + 1, j) = p(i, j + 1) \] (2.10)

or

\[ \gcd(p(i + 1, j), p(i, j + 1)) = 1. \] (2.11)

In the former case, $p(i, j)$ is a polynomial of $i + j$ (see [5, Lemma 3] or [14, Lemma 3.3]). For this case we do not have a bound. We denote by $v_3(i + j)$ the product of all irreducible factors $p(i, j)$ of $v(i, j)$ that satisfy (2.10). In the later case, by hypothesis ($H1$), we have

\[ \gcd(p(i + 1, j), g_1(i, j)g_2(i, j)g_2(i, j + 1)) = 1 \]

and

\[ \gcd(p(i, j + 1), g_1(i, j)g_2(i, j)g_1(i + 1, j)) = 1. \]

Thus,

\[ p^l(i, j) \mid \gcd(r_1(i - 1, j)s_2(i - 1, j), r_2(i, j - 1)s_1(i, j - 1)). \]

Let $v_4(i, j)$ denote the product of all irreducible factors $p(i, j)$ of $v(i, j)$ that satisfy (2.11). Then we have (2.7).

2. Suppose $p$ is an irreducible factor of $g'_1$ and $p^l \mid g'_1$ for some non-negative integer $l$. If $p(i, j) \mid v(i, j + 1)$, then $p(i, j - 1) \mid v(i, j)$. By hypothesis ($H1$), $p(i, j - 1) = p(i, j)$, which implies $p(i, j) \mid v(i, j)$, contradicting to hypothesis ($H2$). Noting further that by hypothesis ($H3$), for any $h_1, h_2 \in \{-1, 0, 1\}$,

\[ \gcd(f_1(i, j), g_1(i, j)) = \gcd(g'_1(i, j), g'_2(i + 1, j + h_1, j + h_2)) = 1, \]

we must have that

\[ p^l(i, j) \mid s_1(i, j)s_2(i, j)g_1(i + 1, j). \]

If $p(i + 1, j) \mid v(i, j + 1)$, then by hypothesis ($H1$), $p(i + 1, j - 1) = p(i, j)$, which implies $p(i, j) \mid v(i, j)$, contradicting to hypothesis ($H2$). Therefore, by hypothesis ($H3$),

\[ p^l(i + 1, j) \mid r_1(i, j)s_2(i, j)g_1(i, j). \]

There are two cases:
• $p(i, j) = p(i + 1, j)$. Then $p(i, j)$ is a polynomial depending only on $j$. For this case we also do not have a bound. We denote by $u_1(j)$ the product of all irreducible factors of $g'_1(i, j)$ that depend only on $j$.

• $\gcd(p(i, j), p(i + 1, j)) = 1$. Then by hypothesis $(H1)$,

$$\gcd(p(i, j), g_1(i + 1, j)) = \gcd(p(i + 1, j), g_1(i, j)) = 1,$$

and hence,

$$p^l(i, j) \mid \gcd(s_1(i, j)s'_2(i, j), r_1(i - 1, j)s'_2(i - 1, j)).$$

Let $u_2(i, j)$ denote the product of all irreducible factors $p(i, j)$ of $g'_1(i, j)$ such that $\gcd(p(i, j), p(i + 1, j)) = 1$. Then we have (2.8).

3. Similarly, suppose $p$ is an irreducible factor of $g'_2$ and $p^l|g'_2$ for some non-negative integer $l$. Then either $p(i, j)$ is a polynomial depending only on $i$ or

$$p^l(i, j) \mid \gcd(s_2(i, j)s'_1(i, j), r_2(i, j - 1)s'_1(i, j - 1)).$$

Let $w_1(i)$ denote product of irreducible factors of $g'_2(i, j)$ that depend only on $i$ and $w_2(i, j)$ denote the product of the rest irreducible factors of $g'_2(i, j)$. Then we have (2.9).

Note that $u_2(i, j)$ have no factors which are free of $i$ and $w_2(i, j)$ have no factors which are free of $j$. We will need this property later for the algorithm EstDen.

### 3. Denominators in Our Telescoping Method

We are now ready to estimate the denominators of $R_1$ and $R_2$ in our telescoping method.

As in the case of single summations, the telescoping algorithm for double summations tries to find an operator

$$L = a_0(n) + a_1(n)N + \cdots a_r(n)N^r$$
and rational functions $R_1(n, i, j), R_2(n, i, j)$ such that

$$LF(n, i, j) = \Delta_i(R_1(n, i, j)F(n, i, j)) + \Delta_j(R_2(n, i, j)F(n, i, j)).$$

(3.1)

Let

$$\frac{F(n, i + 1, j)}{F(n, i, j)} = r_1(n, i, j), \quad \frac{F(n, i, j + 1)}{F(n, i, j)} = r_2(n, i, j),$$

(3.2)

and $d(n, i, j)$ be the common denominator of

$$\frac{F(n + 1, i, j)}{F(n, i, j)}, \ldots, \frac{F(n + r, i, j)}{F(n, i, j)}.$$

Then there exists a polynomial $c(n, i, j)$, not necessarily being coprime to $d$, such that

$$\frac{LF(n, i, j)}{F(n, i, j)} = \sum_{l=0}^r a_l(n) \frac{F(n + l, i, j)}{F(n, i, j)} = \frac{c(n, i, j)}{d(n, i, j)}.$$  

(3.3)

Note that $c$ is related to the polynomials $a_0, a_1, \ldots, a_r$ but $d$ is independent of them.

Now, (3.1) can be written in the form of (2.1):

$$LF(n, i, j) = \Delta_i(R'_1(n, i, j)LF(n, i, j)) + \Delta_j(R'_2(n, i, j)LF(n, i, j)),$$

where

$$R'_1(n, i, j) = R_1(n, i, j) \frac{d(n, i, j)}{c(n, i, j)} \quad \text{and} \quad R'_2(n, i, j) = R_2(n, i, j) \frac{d(n, i, j)}{c(n, i, j)}.$$

This suggests us to assume

$$R_1(n, i, j) = \frac{1}{d(n, i, j)} f_1(n, i, j) \quad \text{and} \quad R_2(n, i, j) = \frac{1}{d(n, i, j)} f_2(n, i, j),$$

(3.4)

where $f_1, g_1$ (or $f_2, g_2$, respectively) are relatively prime polynomials.

Since the following discussion is independent of $n$, we omit the variable $n$ for convenience. For example, we write $R_1(i, j)$ instead of $R_1(n, i, j)$. Using these notations, we have

9
Theorem 3.1 Suppose the polynomials $g_1, g_2$ in (3.4) satisfy the hypotheses (H1)–(H3). Suppose further that for any $h_1, h_2 \in \{-1, 0, 1\}$,
\[
\gcd(g_1(i, j), d(i + h_1, j + h_2)) = \gcd(g_2(i, j), d(i + h_1, j + h_2)) = 1. \quad (3.5)
\]
Then $g_1(i, j), g_2(i, j)$ can be factored into polynomials:
\[
g_1(i, j) = v_1(i) v_2(j) v_3(i + j) v_4(i, j) u_1(j) w_2(i, j),
\]
\[
g_2(i, j) = v_1(i) v_2(j) v_3(i + j) v_4(i, j) w_1(i) w_2(i, j),
\]
such that
\[
v_1(i) | r_1(i - 1, j) s_2'(i - 1, j),
\]
\[
v_2(j) | r_2(i, j - 1) s_1'(i, j - 1),
\]
\[
v_4(i, j) | \gcd(r_1(i - 1, j) s_2'(i - 1, j), r_2(i, j - 1) s_1'(i, j - 1)),
\]
\[
u_2(i, j) | \gcd(s_1(i, j) s_2'(i, j), r_1(i - 1, j) s_2'(i - 1, j)),
\]
\[
w_2(i, j) | \gcd(s_2(i, j) s_1'(i, j), r_2(i, j - 1) s_1'(i, j - 1)),
\]
where
\[
s_1'(i, j) = s_1(i, j) / \gcd(s_1(i, j), s_2(i, j)),
\]
\[
s_2'(i, j) = s_2(i, j) / \gcd(s_1(i, j), s_2(i, j)). \quad (3.6)
\]

Proof. Substituting (3.4) into (3.1) and dividing $F(i, j)$ on both sides, we obtain
\[
\frac{c(i, j)}{d(i, j)} = \frac{r_1(i, j) f_1(i + 1, j)}{s_1(i, j) d(i + 1, j) g_1(i + 1, j)} - \frac{f_1(i, j)}{d(i, j) g_1(i, j)}
\]
\[
+ \frac{r_2(i, j) f_2(i, j + 1)}{s_2(i, j) d(i, j + 1) g_2(i, j + 1)} - \frac{f_2(i, j)}{d(i, j) g_2(i, j)}, \quad (3.7)
\]
i.e.,
\[
c(i, j) = \frac{r_1(i, j) d(i, j)}{s_1(i, j) d(i + 1, j) g_1(i + 1, j)} \frac{f_1(i + 1, j)}{g_1(i, j)} - \frac{f_1(i, j)}{g_1(i, j)}
\]
\[
+ \frac{r_2(i, j) d(i, j)}{s_2(i, j) d(i, j + 1) g_2(i, j + 1)} \frac{f_2(i, j + 1)}{g_2(i, j)} - \frac{f_2(i, j)}{g_2(i, j)}.
\]
Let
\[
\tilde{r}_1(i, j) = r_1(i, j) d(i, j), \quad \tilde{s}_1(i, j) = s_1(i, j) d(i + 1, j),
\]
\[
\tilde{r}_2(i, j) = r_2(i, j) d(i, j), \quad \tilde{s}_2(i, j) = s_2(i, j) d(i, j + 1).
\]
All discussion in the proof of Theorem 2.1 still holds. Thus, we have

\[ v_1(i) | \tilde{r}_1(i - 1, j)\tilde{s}_2'((i - 1, j), \]
\[ v_2(j) | \tilde{r}_2(i, j - 1)\tilde{s}_1'(i, j - 1), \]
\[ v_4(i, j) | \gcd(\tilde{r}_1(i - 1, j)\tilde{s}_2'(i - 1, j), \tilde{r}_2(i, j - 1)\tilde{s}_1'(i, j - 1)), \] \hspace{1cm} (3.8)
\[ u_2(i, j) | \gcd(\tilde{s}_1(i, j)\tilde{s}_2(i, j), \tilde{r}_1(i - 1, j)\tilde{s}_2'(i - 1, j)), \]
\[ w_2(i, j) | \gcd(\tilde{s}_2(i, j)\tilde{s}_1'(i, j), \tilde{r}_2(i, j - 1)\tilde{s}_1'(i, j - 1)), \]

where

\[ \tilde{s}_1'(i, j) = \tilde{s}_1(i, j) / \gcd(\tilde{s}_1(i, j), \tilde{s}_2(i, j)), \]
\[ \tilde{s}_2'(i, j) = \tilde{s}_2(i, j) / \gcd(\tilde{s}_1(i, j), \tilde{s}_2(i, j)). \]

Since we have (3.5), we may replace \( \tilde{r}_1, \tilde{s}_1, \tilde{r}_2, \tilde{s}_2 \) by \( r_1, s_1, r_2, s_2 \) in (3.8), respectively.

4. A Telescoping Method for Bivariate Hypergeometric Terms

Theorem 3.1 enables us to choose the denominators in the telescoping algorithm. Basically, we will use certain factors appearing in the bounds of the denominators as estimates of the denominators. In many cases, this approach seems to work quite efficiently although we are not able to give formula to bound the denominators because certain factors are not bounded in Theorem 3.1. Roughly speaking, the divisibility considerations in our method serve as a guide to guess the factors in the denominators. In fact, the estimated denominators are much smaller than the theoretical bounds given by Theorem 3.1. Only \( u_2(i, j) \) and \( w_2(i, j) \) are set to their theoretical bounds, while \( v_2(j), v_3(i + j), v_4(i, j) \) are set to 1, \( u_1(j) \) and \( w_1(i) \) are set to factors of \( s_1(i, j)s_2'(i, j) \), and \( v_1(i) \) is set to a factor of its theoretical bound. See the following algorithm EstDen.

Algorithm EstDen

Input: A hypergeometric term \( F(n, i, j) \).

Output: Estimated denominators \( g_1(i, j) \) and \( g_2(i, j) \) for bivariate Gosper’s algorithm.

1. Calculate \( r_1, r_2, s_1, s_2, s_1', s_2' \) defined by (3.2) and (3.6);
2. Set
\[ v_1(i) := \text{the maximal factor of } r_1(i, j)s'_2(i, j) \text{ depending only on } i; \]
\[ v_2(j) := \text{the maximal factor of } r_2(i, j)s'_1(i, j) \text{ depending only on } j; \]
and
\[ v(i) := \gcd(v_1(i - 1), v_2(i - 1)); \]

3. Set
\[ u_1(j) := \text{the maximal factor of } s_1(i, j)s'_2(i, j) \text{ depending only on } j; \]
\[ w_1(i) := \text{the maximal factor of } s_1(i, j)s'_2(i, j) \text{ depending only on } i; \]

4. Set \( u_2(i, j) \) to be the maximal factor of
\[ \gcd(s_1(i, j)s'_2(i, j), r_1(i - 1, j)s'_2(i - 1, j)) \]
which depends on \( i \);
Set \( w_2(i, j) \) to be the maximal factor of
\[ \gcd(s_1(i, j)s'_2(i, j), r_2(i, j - 1)s'_1(i, j - 1)) \]
which depends on \( j \).

5. Return \( g_1(i, j) := v(i)u_1(j)w_2(i, j) \) and \( g_2(i, j) := v(i)w_1(i)w_2(i, j) \).

**Remark.** Let \( f(i, j) \) be a polynomial in \( i, j \) and \( a \) be a new variable. Then the maximal factor of \( f(i, j) \) depending only on \( i \) can be obtained by
\[ \gcd(f(i, j), f(i, j + a)), \]
and the maximal factor of \( f(i, j) \) depending on \( i \) can be obtained by
\[ f(i, j)/\gcd(f(i, j), f(i + a, j)). \]

We are now ready to describe our telescoping method for double summations:

**Method BiZeil**

**Input:** A hypergeometric term \( F(n, i, j) \).

**Output:** An operator \( L \) and rational functions \( R_1 \) and \( R_2 \) such that (3.1) holds if succeed.

1. Using algorithm EstDen to obtain \( g_1 \) and \( g_2 \).
2. Set the order \( r \) of the linear difference operator \( L \) to be zero.

3. For the order \( r \), calculate the common denominator \( d(n, i, j) \) of
\[
\frac{F(n+1, i, j)}{F(n, i, j)}, \ldots, \frac{F(n+r, i, j)}{F(n, i, j)}.
\]
(If \( r = 0 \), then take \( d(n, i, j) = 1 \).)

4. Set the degrees of \( f_1 \) and \( f_2 \) to be one more than those of \( d \cdot g_1 \) and \( d \cdot g_2 \), respectively.

5. Solve the equation (3.7) by undeterminate coefficients method to obtain \( a_0, a_1, \ldots, a_r \) and \( f_1, f_2 \).

6. If \( a_i \neq 0 \) for some \( i \in \{0, \ldots, r\} \), then return \( L, f_1/(d \cdot g_1), f_2/(d \cdot g_2) \) and we are done.

If \( a_i = 0 \) for all \( i \in \{0, \ldots, r\} \), but \( \deg f_1 - \deg (d \cdot g_1) \leq 2 \), then increase the degrees of \( f_1 \) and \( f_2 \) by one and repeat step 5.
Otherwise, set \( r := r + 1 \) and repeat the process from step 3.

Remarks.

1. In many cases, \( g_1(i, j) \) and \( g_2(i, j) \) can be further reduced by cancelling a factor of degree 1 and a factor of degree 2 from \( g_1 \) and \( g_2 \), respectively. This cancellation may reduce the time of calculation.

2. In all the following examples except Example 4, the degree of the numerator of \( R_1 \) (\( R_2 \)) is one more than that of the denominator. While in Example 4, the difference is two.

The degree bounds can be interpreted as follows. Let \( t_1, t_2, t_3, t_4 \) be the four terms of the right hand side of (3.7) after multiplying the common denominator. In most cases, the leading terms of \( t_1 \) and \( t_2 \) (\( t_3 \) and \( t_4 \), respectively) are cancelled.

3. There is a way to speed up the computation in Step 5. Given \( g_1 \) and \( g_2 \), we may derive part of the factors of \( f_1 \) and \( f_2 \) by divisibility. For example, suppose (3.7) becomes
\[
\frac{c(i, j)}{d(i, j)} = \frac{u_1(i, j)}{v_1(i, j)} f_1(i + 1, j) - \frac{f_1(i, j)}{w_1(i, j)} + \frac{u_2(i, j)}{v_2(i, j)} f_2(i, j + 1) - \frac{f_2(i, j)}{w_2(i, j)},
\]
after substituting and simplification. Suppose further that $D(i, j)$ is the common denominator of the above equation. Then we immediately have that $f_1(D/w_1)$ is divisible by $q_1 = \gcd(cD/d, u_1D/v_1, u_2D/v_2, D/w_2)$ and $f_1(i+1, j)u_1D/v_1$ is divisible by $q_2 = \gcd(cD/d, D/w_1, u_2D/v_2, D/w_2)$, and hence,

$$\frac{q_1}{\gcd(D/w_1, q_1)} \quad \text{and} \quad \frac{q_2}{\gcd(u_1D/v_1, q_2)}$$

are factors of $f_1(i, j)$ and $f_1(i+1, j)$, respectively.

5. Examples

In the following examples, let $F$ denote the summand of the left hand side of the identity.

**Example 1.** The Andrews-Paule identity:

$$\sum_{i=0}^{n} \sum_{j=0}^{n} \binom{i+j}{i} \binom{4n-2i-2j}{2n-2i} = (2n+1)\binom{2n}{n}^2. \quad (5.1)$$

It was proved by G. Andrews and P. Paule [6, 7] by establishing a more general identity

$$\sum_{i=0}^{[\frac{m}{2}]} \sum_{j=0}^{[\frac{n}{2}]} \binom{i+j}{i} \binom{m+n-2i-2j}{n-2i} = \frac{\frac{m+n+1}{2}! \frac{m+n+2}{2}!}{\frac{m}{2}! \frac{m+1}{2}! \frac{n}{2}! \frac{n+1}{2}!}.$$ 

Using the method BiZeil, we can deal with (5.1) directly. In fact, we have

$$g_1(i, j) = (2n-2i+1)(n-i+1)(j+1)^2, \quad g_2(i, j) = (2n-2i+1)(n-i+1)(i+1)^2.$$ 

Cancelling the factors $(n-i+1)$ and $(i+1)^2$ from $g_1(i, j)$ and $g_2(i, j)$, respectively, we obtain

$$\tilde{g}_1(i, j) = (2n-2i+1)(j+1)^2 \quad \text{and} \quad \tilde{g}_2(i, j) = (2n-2i+1)(n-i+1).$$

Finally, we get (in 1 second)

$$(2n+1)F(n, i, j) = \Delta_iR_1F(n, i, j) + \Delta_jR_2F(n, i, j).$$
where
\[ R_1 = \frac{i^2(6n^2 + 5n + 1 + 6jn^2 + jn - j - in + 2in^2 - 2i - 4j^2n - 2j^2 - 3ij - 4ijn)}{(2n - 2i + 1)(1 + j)^2}, \]
\[ R_2 = \frac{-2n^2 + 2jn^2 + 6in^2 + 9in + 3jn - 4ijn - 4i^2n - n + j - 3ij + 2i - 4i^2}{(2n - 2i + 1)}, \]
which are the same as given in [19, p. 85]. Summing \( i, j = 0, \ldots, n \), we get
\[
(2n + 1) \sum_{i=0}^{n} \sum_{j=0}^{n} F(n, i, j)
= \sum_{i=0}^{n} \left( R_2 F(n, i, n + 1) - R_2 F(n, i, 0) \right) + \sum_{j=0}^{n} \left( R_1 F(n, n + 1, j) - R_1 F(n, 0, j) \right)
\]
Note that there is only one nonzero term \( R_1 F(n, n + 1, n) \) of the second summation. While applying Gosper’s algorithm to the first summand, we obtain
\[
\sum_{i=0}^{n} \left( R_2 F(n, i, n + 1) - R_2 F(n, i, 0) \right) = G(n + 1) - G(0),
\]
where
\[ G(i) = \frac{(-2n + i - 1)(-4n + 2i - 1)i}{-1 + 2i - 2n} \frac{4n - 2i}{2n - 2i}. \]
Simplifying \( G(n + 1) - G(0) + R_1 F(n, n + 1, n) \), we finally get (5.1).

**Example 2.** Carlitz’s identity [9] (see Also [20, Example 6.1.2]):
\[
\sum_{i} \sum_{j} \binom{i + j}{i} \binom{n - i}{j} \binom{n - j}{n - i - j} = \sum_{l=0}^{n} \binom{2l}{l}.
\]
We have
\[ g_1(i, j) = (j + 1)^2(-n + j), \quad g_2(i, j) = (i + 1)^2(-n + i). \]
Cancelling the factors \(-n + j) and \((i + 1)(-n + i)\), we obtain
\[ \tilde{g}_1(i, j) = (j + 1)^2 \quad \text{and} \quad \tilde{g}_2(i, j) = i + 1. \]
Notice that the common denominator of
\[
\frac{F(n+1,i,j)}{F(n,i,j)} \quad \text{and} \quad \frac{F(n+2,i,j)}{F(n,i,j)}
\]
is \((-n+i-1+j)^2(-n+i-2+j)^2\). We finally get (in 2 seconds)
\[
L = (4n+6)-(8+5n)N+(n+2)N^2,
\]
and
\[
R_1 = \left(-i^2(-n+i-1)(36-10ji^2n-13j^2ni+60j^2+60ji-2i^2-38j^2i\right.
\]
\[-8ji^2+10i^3+36n^3-14jn^3-2i^4-92jn^2+8i^2n-80in+5j^2n^2
\]+ \left.8j^2i^2+88jin+42j^2n-172jn+24jin^2+5i^2n^2+3i^3n-54in^2+88n^2+4j^3n
\right.
\[-90j+6j^3-40i+5n^4+90n)\left((-n+i-1+j)^2(-n+i-2+j)^2(j+1)^2\right),
\]
\[
R_2 = \left((64-19ji^2n-6j^2ni+14j^2i+74ji+54i^2-10j^2i-36ji^2+2i^3+39n^3
\right.
\left.-16in^3-9jn^3-4i^4+6ji^3-53jn^2+50i^2n-176in+4j^2n^2+4j^2i^2+5n^4
\right.
\left.+83jin+16j^2n-100jn+22jin^2+11n^2+4i^3n-93in^2+112n^2-60j
\right.
\left.-108i+140n)(-n-1+j)\right)\left((-n+i-2+j)^2(-n+i-1+j)^2\right),
\]
such that
\[
LF(n,i,j) = \Delta_i R_1 F(n,i,j) + \Delta_j R_2 F(n,i,j), \quad (5.2)
\]

By summing (5.2) over \(i, j\) one sees that \(L\) annihilates the double sum on the left hand side. Using Zeilberger’s algorithm we arrive at the same recursion for the right hand side. Then the identity follows from the initial values \(n = 0, 1\).

The proofs of the following examples are similar to that of Example 2. We only need to give \(g_1, g_2\) and \(L, R_1, R_2\). Then these identities can be verified by checking the initial values.

**Example 3.** Carlitz’s identity [8] (see also [20, Example 6.1.3]):
\[
\sum_{i} \sum_{j} \binom{i+j}{i} \binom{m-i+j}{j} \binom{n-j+i}{i} \binom{m+n-i-j}{m-i}
\]
\[
= \frac{(m+n+1)!}{m!n!} \sum_{k} \frac{1}{2k+1} \binom{m}{k} \binom{n}{k}.
\]
By cancelling the factors \((1 + j)\) and \((i + 1)^2\), we obtain
\[
\tilde{g}_1(i, j) = (n - j + i)(1 + j) \quad \text{and} \quad \tilde{g}_2(i, j) = m - i + j
\]
Notice that the common denominator of
\[
\frac{F(n + 1, i, j)}{F(n, i, j)} \quad \text{and} \quad \frac{F(n + 2, i, j)}{F(n, i, j)}
\]
is \((-n + j - 1)^2(-n + j - 2)^2\), which is denoted by \(d(i, j)\). We finally get (in 37 seconds)
\[
L = 2(m + 3 + n)(2 + m + n)^2 - (3m + 2nm + 4n^2 + 14 + 15n)(n + m + 3)N + (2n + 5)(n + 2)^2N^2,
\]
and the denominators of \(R_1, R_2\) are \(d(i, j)\tilde{g}_1(i, j)\) and \(d(i, j)\tilde{g}_2(i, j)\), respectively. The degrees of denominators and numerators of \(R_1, R_2\) are both less than those given in [20].

**Example 4.** The Apéry-Schmidt-Strehl identity [18]:

\[
\sum_i \sum_j \binom{n}{j} \binom{n+j}{j} \binom{j}{i}^3 = \sum_k \binom{n}{k}^2 \binom{n+k}{k}^2.
\]

By cancelling the factors \((-j - 1 + i)\) and \((i + 1)^2\), we obtain
\[
\tilde{g}_1(i, j) = (-j - 1 + i)^2 \quad \text{and} \quad \tilde{g}_2(i, j) = i + 1
\]
Notice that the common denominator of
\[
\frac{F(n + 1, i, j)}{F(n, i, j)} \quad \text{and} \quad \frac{F(n + 2, i, j)}{F(n, i, j)}
\]
is \((n + 2 - j)(n + 1 - j)\). We finally get (in 1 second)
\[
L = (n + 1)^3 - (3 + 2n)(17n^2 + 51n + 39)N + (n + 2)^3N^2,
\]
and
\[
R_1 = \left( -2\tilde{i}^2(3 + 2n)(-10 + 30j^2 - 49n^2 - j^3 - 4n^4 - 24n^3 - 2n^2\tilde{i}^2 + n^2\tilde{i} - 6n\tilde{i}^2 + 3n^2ji + n^2ji + 3n^2j^2 - 3j^3i + 3ji - 4\tilde{i}^2 - 2\tilde{j}^2i - 2ji^2 + 11n^2j^2 + 6n^2j + 33n\tilde{j}^2 + 18n\tilde{j} - 6\tilde{j}^4 + 2i + 15j - 39n) \right) / ((n + 2 - j)(n + 1 - j)(-j - 1 + i)^2),
\]
The rational functions $R_1, R_2$ are simpler than those given in [18]. The operator $L$ was used by Apéry in his proof of the irrationality of $\zeta(3)$ and Chyzak and Salvy obtained it using Ore algebras [11].

Example 5. The Strehl identity [18]:

$$
\sum_{i,j} \left( \binom{n}{j} \binom{n+j}{j} \binom{2i}{i} \right)^2 \frac{(2i)^2}{(i-j)^2} = \sum_k \binom{n}{k}^3 \binom{n+k}{k}^3.
$$

(5.3)

By cancelling the factor $(-3i - 3 + j)(-3i - 2 + j)$ from $g_2$, we obtain

$$
\tilde{g}_1(i, j) = (j + 1 - i)^3 \quad \text{and} \quad \tilde{g}_2(i, j) = (-3i - 1 + j)(i + 1)^3.
$$

Notice that the denominator of $F(n+1, i, j)$

$$
\frac{F(n+1, i, j)}{F(n, i, j)}, \ldots, \frac{F(n+6, i, j)}{F(n, i, j)}
$$

is $(n+1-j)(n+2-j)\cdots(n+6-j)$, which is denoted by $d(i, j)$. We finally get (in 2510 seconds) a linear difference operator $L$ of order 6 and the denominators of $R_1, R_2$ are $d(i, j)\tilde{g}_1(i, j)$ and $d(i, j)\tilde{g}_2(i, j)$, respectively.

The operator $L$ is the same as the operator obtained by applying Zeilberger’s algorithm to the right hand side of (5.3).

Example 6. The Graham-Knuth-Patashnik identity [13, p. 172]:

$$
\sum_{j,k} (-1)^{j+k} \binom{j+k}{k+l} \binom{n}{j} \binom{s+n-j-k}{m-j} = (-1)^{l} \binom{n+r}{n+l} \binom{s-r}{m-n-l}.
$$

(5.4)

By cancelling the factor $(j+1)(j+1-l)$ from $g_2$, we obtain

$$
\tilde{g}_1(j, k) = (k+1)(k+l+1) \quad \text{and} \quad \tilde{g}_2(j, k) = 1.
$$

Notice that the denominator of $\frac{F(r+1, j, k)}{F(r, j, k)}$ is $r-j+1$, which is denoted by $d(j, k)$. We finally get (in 8 seconds) a linear difference operator with respect to the variable $r$:

$$
L = (r+n+1)(n+s+l-m-r) + (r-l+1)(r-s)R
$$
and the denominators of $R_1, R_2$ are $d(j, k)\tilde{g}_1(j, k)$ and $d(j, k)\tilde{g}_2(j, k)$, respectively. Then (5.4) follows from the evaluation of the initial value $(r = 0)$ by Zeilberger’s algorithm:

$$
\sum_k (-1)^k \binom{k}{k+l} \binom{n}{k} \binom{s+n-k}{m} = (-1)^l \binom{n}{n+l} \binom{s}{m-n-l}.
$$

**Example 7.** The Petkovšek-Wilf-Zeilberger identity [16, p. 33]:

$$
\sum_r \sum_s (-1)^{n+r+s} \binom{n}{r} \binom{n+s}{s} \binom{n+r}{r} \binom{2n-r-s}{n} = \sum_k \binom{n}{k}^4.
$$

By cancelling the factors $s+1$ and $(r+1)^2$, we obtain

$$
\tilde{g}_1(r, s) = (n+r)(n+1-r)(s+1) \quad \text{and} \quad \tilde{g}_2(r, s) = (n+r)(n+1-r).
$$

Notice that the common denominator of

$$
\frac{F(n+1, r, s)}{F(n, r, s)} \quad \text{and} \quad \frac{F(n+2, r, s)}{F(n, r, s)}
$$

is

$$(n+1)(n+2)(n+1-r)(n+1-s)(n+2-s)(n-r-s+1)(n+2-r-s),$$

which is denoted by $d(r, s)$. We finally get (in 35 seconds)

$$
L = 4(4n + 5)(4n + 3)(n + 1) + 2(2n + 3)(3n^2 + 9n + 7)N - (n + 2)^3N^2
$$

is a linear difference operator and the denominators of $R_1, R_2$ are $d(r, s)\tilde{g}_1(r, s)$ and $d(r, s)\tilde{g}_2(r, s)$, respectively. The recursion is the same as that obtained by applying Zeilberger’s algorithm to the right hand side of (5.5).

**Acknowledgments.** We would like to thank the referees for valuable suggestions leading to a significant improvement of an earlier version. The authors are grateful to Professor P. Paule for many helpful discussions and comments. This work was done under the auspices of the “973” Project on Mathematical Mechanization, the National Science Foundation, the Ministry of Education, and the Ministry of Science and Technology of China.
